
Algorithm 1 Get Distances. The distance is the euclidean distance between the values of the observed equation and a neighbor's equation, after both were evaluated with the time steps of the observed equation.

Input: Direct successors and an observed equation.

Output: List of the distance of all neighbors with respect to the observation.

```
1: procedure GET_DISTANCES(directSuccessors, observedEquation)
2:   timeSteps  $\leftarrow$  observedEquation.timeSteps
3:   observedFunction  $\leftarrow$  observedEquation.fittedFunction
4:   for each neighbor  $\in$  directSuccessors do
5:     neighborFunction  $\leftarrow$  neighbor.fittedFunction
6:     neighborPoints  $\leftarrow$  evaluatefunction(neighborFunction, timeSteps)
7:     observedPoints  $\leftarrow$  evaluatefunction(observedFunction, timeSteps)
8:     distance  $\leftarrow$  getEuclideanDistance(observedPoints, neighborPoints)
9:     distanceList.push(distance)
10:  end for
11:  return distanceList
12: end procedure
```
